Automatic Identification of Shunts by COstatus® PICU Monitor

Transonic Systems Inc., Ithaca, NY

BACKGROUND
The shape of dilution curve changes dramatically after an indicator passes through the cardiopulmonary system in the presence of intra-cardiac shunts and a patent ductus arteriosus (PDA).

OBJECTIVE
To develop an accurate algorithm for shunt identification and apply it to archived clinical data.

STUDY
- A mathematical model of indicator movement through the cardiopulmonary system for three scenarios was developed. They were:
  1) No shunt;
  2) Right-to-left shunt;
  3) Left-to-right shunt.
- Three parameters of the dilution curve were examined:
  1) appearance time;
  2) asymmetry;
  3) curve width.
- Three possible scenarios were defined based on the probability “P” of shunt identification:
  1) No shunt, P<5%;
  2) Possible shunt; 5%<P<90%;
  3) Shunt identified P>90%
- In the model, the values for cardiac output, heart size and heart rate were varied.
- In play-back mode the developed algorithm was applied to a clinical data archive of 1,188 dilution curves collected from adults (n=131) and from children (n=112) weighing between 0.9 -130 kg.

RESULTS
Sensitivity of the method was 94%, and false positive diagnostic was 0.9%.

STUDY’S CONCLUSIONS
- Automatic identification of shunts and PDA with the COstatus® monitor yielded acceptable accuracy.
- The new COstatus® monitor identifies the presence of intra-cardiac shunts based on a developed algorithm, in addition to measuring cardiac output and blood volumes.
- A follow-up step will be to quantify the observed shunt flow values.
